1. Directional Derivative

1.1. Definition

The directional derivative of a multivariable function at a given point is a measure of the rate of change of the function in a particular direction at that point. It is a generalization of the concept of the derivative of a function of one variable, which measures the rate of change of the function in the direction of the x-axis.

The directional derivative of a function f(x,y) at a point $\left(x_0,y_0\right)$ in the direction of a unit vector $\boldsymbol{u}=(a\,b)$ is given by:

$$\frac{\partial f}{\partial \boldsymbol{u}} \Big(\boldsymbol{x}_0, \boldsymbol{y}_0\Big) = \nabla f \Big(\boldsymbol{x}_0, \boldsymbol{y}_0\Big) \cdot \boldsymbol{u} = \Big(\frac{\partial f}{\partial \boldsymbol{x}} \Big(\boldsymbol{x}_0, \boldsymbol{y}_0\Big) \, \frac{\partial f}{\partial \boldsymbol{y}} \Big(\boldsymbol{x}_0, \boldsymbol{y}_0\Big) \Big) \cdot (a \; b)$$

Where $\nabla f \left(x_0, y_0 \right)$ is the gradient vector of the function at the point $\left(x_0, y_0 \right)$, and $\frac{\partial f}{\partial x} \left(x_0, y_0 \right)$ and $\frac{\partial f}{\partial y} \left(x_0, y_0 \right)$ are the partial derivatives of the function with respect to x and y respectively.

The directional derivative can be thought of as the projection of the gradient vector onto the direction specified by the unit vector u. It tells us the rate of change of the function in the direction of u at the point (x_0, y_0) .

1.2. Example

To find the directional derivative of the function $f(x,y) = x^2 \sin 2y$ in the direction of the vector $\mathbf{u} = (\cos \sin)$, we need to first find the gradient vector of the function at the given point.

The partial derivatives of f with respect to x and y are:

$$\frac{\partial f}{\partial x} = 2x\sin 2y$$

$$\frac{\partial f}{\partial y} = 2x^2 \cos 2y$$

The gradient vector of the function at a point (x_0, y_0) is given by:

$$\nabla f \Big(x_0, y_0 \Big) = \Big(\tfrac{\partial f}{\partial x} \Big(x_0, y_0 \Big) \, \tfrac{\partial f}{\partial y} \Big(x_0, y_0 \Big) \Big) = \Big(2 x_0 \sin 2 y_0 \, 2 x_0^2 \cos 2 y_0 \Big)$$

The directional derivative of the function in the direction of \boldsymbol{u} at the point $\left(x_0,y_0\right)$ is then given by:

$$\frac{\partial f}{\partial \boldsymbol{u}} \left(\boldsymbol{x}_0, \boldsymbol{y}_0 \right) = \nabla f \left(\boldsymbol{x}_0, \boldsymbol{y}_0 \right) \cdot \boldsymbol{u} = \left(2 \boldsymbol{x}_0 \sin 2 \boldsymbol{y}_0 \ 2 \boldsymbol{x}_0^2 \cos 2 \boldsymbol{y}_0 \right) \cdot (\cos \sin)$$

We can evaluate this expression to find the directional derivative. For example, if $\left(x_0,y_0\right)=(1,1)$, then the directional derivative is:

$$\frac{\partial f}{\partial u}(1,1) = (2 \cdot 1 \cdot \sin 2 \cdot 1 \cdot 2 \cdot 1^2 \cos 2 \cdot 1) \cdot (\cos \sin) = (\sin 2 \cos 2) \cdot (\cos \sin) = \sin^2 2 + \cos^2 2 = 1$$
